Chapter 5 Remote Invocation
Chapter 5 Remote Invocation

5.1 Introduction

5.2 Request-reply protocols

5.3 Remote procedure call

5.4 Remote method invocation

5.5 Case study: Java RMI

5.6 Summary
5.1 Introduction

• Programming Models for Distributed Communications
  – Request-reply protocols: message passing in client-server computing
  – Remote Procedure Calls – Client programs call procedures in server programs
  – Remote Method Invocation – Objects invoke methods of objects on distributed hosts
  – Event-based Programming Model – Objects receive notice of events in other objects in which they have interest
• Middleware: software that allows a level of programming beyond processes and message passing
  – Uses protocols based on messages between processes to provide its higher-level abstractions such as remote invocation and events
  – Supports location transparency
  – Usually uses an *interface definition language (IDL)* to define interfaces
5.2 Request-reply Protocols

Figure 5.2 Request-reply communication

- Typical client-server interaction
  - Usually synchronous, reliable
- Three operations:
  - client: doOperation
  - server: getRequest, sendReply
Operations of the request-reply protocol

Figure 5.3

*public byte[] doOperation (RemoteRef s, int operationId, byte[] arguments)*

sends a request message to the remote server and returns the reply. The arguments specify the remote server, the operation to be invoked and the arguments of that operation.

*public byte[] getRequest ();*

acquires a client request via the server port.

*public void sendReply (byte[] reply, InetAddress clientHost, int clientPort);*

sends the reply message reply to the client at its Internet address and port.
Figure 5.4 Request-reply message structure

<table>
<thead>
<tr>
<th>messageType</th>
<th>int  (0=Request, 1=Reply)</th>
</tr>
</thead>
<tbody>
<tr>
<td>requestId</td>
<td>int</td>
</tr>
<tr>
<td>remoteReference</td>
<td>RemoteRef</td>
</tr>
<tr>
<td>operationId</td>
<td>int or Operation</td>
</tr>
<tr>
<td>arguments</td>
<td>array of bytes</td>
</tr>
</tbody>
</table>
## Figure 5.5 RPC exchange protocols

<table>
<thead>
<tr>
<th>Name</th>
<th>Messages sent by</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Client</td>
</tr>
<tr>
<td>R</td>
<td>Request</td>
</tr>
<tr>
<td>RR</td>
<td>Request</td>
</tr>
<tr>
<td>RRA</td>
<td>Request</td>
</tr>
</tbody>
</table>

- **R protocol**: used when no value to be returned and the client requiring no confirmation that the operation has been executed.
- **RR protocol**: used for most client-server exchanges.
- **RRA protocol**: The *Acknowledge reply message* contains the requestId from the reply message being acknowledged to enable the server to discard entries from its history.

5.3 Remote Procedure Call

In RPC, procedures on remote machines can be called as if they are procedures in the local address space.

5.3.1 Design Issues for RPC

• Three issues
  – Interfaces
  – Call semantics: Three main choices to provide different delivery guarantees
    • Retry request messages: Controls whether to retransmit the request message until either a reply is received or the server is assumed to have failed
    • Duplicate filtering: Controls when retransmissions are used and whether to filter out duplicate requests at the server
    • Retransmission of results: Controls whether to keep a history of result messages to enable lost results to be retransmitted without re-executing the operations at the server
  – Transparency
    • Remote calls should be made transparent in the sense that the syntax of a remote call is the same as that of a local invocation, but differently expressed in their interfaces
Interfaces

• Interfaces in Programming Languages
  – Current PL allow programs to be developed as a set of modules that communicate with each other. Permitted interactions between modules are defined by *interfaces*
  – A specified interface can be implemented by different modules without the need to modify other modules using the interface

• Interfaces in Distributed Systems
  – When modules are in different processes or on different hosts there are limitations on the interactions that can occur. Only actions with parameters that are fully specified and understood can communicate effectively to request or provide services to modules in another process
  – A service interface allows a client to request and a server to provide particular services
  – A remote interface allows objects to be passed as arguments to and results from distributed modules

• Object Interfaces
  – An interface defines the signatures of a set of methods, including arguments, argument types, return values and exceptions. Implementation details are not included in an interface. A class may implement an interface by specifying behavior for each method in the interface. Interfaces do not have constructors
Invocation Semantics

• Error handling for delivery guarantees
  – Retry request message: whether to retransmit the request message until either a reply is received or the server is assumed to have failed
  – Duplicate filtering: when retransmissions are used, whether to filter out duplicate requests at the server
  – Retransmission of results: whether to keep a history of result messages to enable lost results to be retransmitted without re-executing the operations

• Choices of invocation semantics
  – Maybe: the method executed once or not at all (no retry nor retransmit)
  – At-least-once: the method executed \textit{at least} once
  – At-most-once: the method executed \textit{exactly} once

<table>
<thead>
<tr>
<th>Fault tolerance measures</th>
<th>Invocation semantics</th>

<tr>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Figure 5.9 Invocation semantics: choices of interest
5.3.2 Implementation of RPC

- **client:** "stub" instead of "proxy" (same function, different names)
  - local call, marshal arguments, communicate the request

- **server:**
  - dispatcher
  - "stub": unmarshal arguments, communicate the results back

![Figure 5.10 Role of client and server stub procedures in RPC in the context of a procedural language](image-url)
5.3.3 Case Study: Sun RPC

• Sun RPC: client-server in the SUN NFS (network file system)
  – UDP or TCP; in other unix OS as well
  – Also called ONC (Open Network Computing) RPC

• Interface Definition Language (IDL)
  – initially XDR is for data representation, extended to be IDL
  – less modern than CORBA IDL and Java
    • program numbers instead of interface names
    • procedure numbers instead of procedure names
    • single input parameter (structs)
  – rpcgen: compiler for XDR
    • client stub; server main procedure, dispatcher, and server stub
    • XDR marshalling, unmarshaling

• Binding (registry) via a local binder - portmapper
  – Server registers its program/version/port numbers with portmapper
  – Client contacts the portmapper at a fixed port with program/version
    numbers to get the server port
  – Different instances of the same service can be run on different computers
    at different ports

• Authentication
  – request and reply have additional fields
  – unix style (uid, gid), shared key for signing, Kerberos
const MAX = 1000;
typedef int FileIdentifier;
typedef int FilePointer;
typedef int Length;
struct Data {
    int length;
    char buffer[MAX];
};
struct writeargs {
    FileIdentifier f;
    FilePointer position;
    Data data;
};

struct readargs {
    FileIdentifier f;
    FilePointer position;
    Length length;
};

program FILEREADWRITE {
    version VERSION {
        void WRITE(writeargs)=1;
        Data READ(readargs)=2;
    }=2;
    } = 9999;
5.4 Remote Method Invocation

Commonalities between RMI and RPC
• Both support programming with interfaces
• Both typically constructed on top of request-reply protocols and can offer a range of call semantics such as at-least-once and at-most-once
• Both offer a similar level of transparency

Differences between RMI and RPC
• Object-oriented
• All objects in an RMI-based system have (global) unique object references, such object references can be passed as parameters, thus offering significantly richer parameter-passing semantics than in RPC
5.4.1 Design Issues for RMI

Five Parts of the Object Model

– An object-oriented program consists of a collection of interacting objects
  • Objects consist of a set of data and a set of methods
  • In DS, object’s data should be accessible only via methods

• **Object References**
  – Objects are accessed by object references
  – Object references can be assigned to variables, passed as arguments, and returned as the result of a method
  – Can also specify a method to be invoked on that object

• **Interfaces**
  – Provide a definition of the signatures of a set of methods without specifying their implementation
  – Define types that can be used to declare the type of variables or of the parameters and return values of methods
The Object Model (Cont.)

• **Actions**
  - Objects invoke methods in other objects
  - An invocation can include additional information as arguments to perform the behavior specified by the method
  - Effects of invoking a method
    1. The state of the receiving object may be changed
    2. A new object may be instantiated
    3. Further invocations on methods in other objects may occur
    4. An exception may be generated if there is a problem encountered

• **Exceptions**
  - Provide a clean way to deal with unexpected events or errors
  - A block of code can be defined to *throw* an exception when errors or unexpected conditions occur. Then control passes to code that *catches* the exception

• **Garbage Collection**
  - Provide a means of freeing the space that is no longer needed
  - Java (automatic), C++ (user supplied)
Distributed Objects

• Physical distribution of objects into different processes or computers in a distributed system
  – Object state consists of the values of its instance variables
  – Object methods invoked by remote method invocation (RMI)
  – Object encapsulation: object state accessed only by the object methods

• Usually adopt the client-server architecture
  – Basic model
    • Objects are managed by servers and
    • Their clients invoke their methods using RMI
  – Steps
    1. The client sends the RMI request in a message to the server
    2. The server executes the invoked method of the object
    3. The server returns the result to the client in another message
  – Other models
    • Chains of related invocations: objects in servers may become clients of objects in other servers
    • Object replication: objects can be replicated for fault tolerance and performance
    • Object migration: objects can be migrated to enhancing performance and availability
Two fundamental concepts: Remote Object Reference and Remote Interface

- Each process contains objects, some of which can receive remote invocations are called *remote objects* (B, F), others only local invocations.
- Objects need to know the *remote object reference* of an object in another process in order to invoke its methods, called *remote method invocations*.
- Every remote object has a *remote interface* that specifies which of its methods can be invoked remotely.
Five Parts of Distributed Object Model

- **Remote Object References**
  - accessing the remote object
  - identifier throughout a distributed system
  - can be passed as arguments

- **Remote Interfaces**
  - specifying which methods can be invoked remotely
  - name, arguments, return type
  - Interface Definition Language (IDL) used for defining remote interface

![Figure 5.4 A Remote Object and Its remote Interface](image)
Five Parts of Distributed Object Model (cont.)

• **Actions**
  – An action initiated by a method invocation may result in further invocations on methods in other objects located in different processes or computers
  – Remote invocations could lead to the instantiation of new objects, i.e., objects M and N of Figure 5.5

• **Exceptions**
  – More kinds of exceptions: i.e., timeout exception
    • RMI should be able to raise exceptions such as timeouts that are due to distribution as well as those raised during the execution of the method invoked

• **Garbage Collection**
  • Distributed garbage collections is generally achieved by cooperation between the existing local garbage collector and an added module that carries out a form of distributed garbage collection, usually based on reference counting

![Figure 5.5 Instantiating Remote Objects](image-url)
Design Issues for RMI

• Two design issues that arise in extension of local method invocation for RMI
  – The choice of invocation semantics
    • Although local invocations are executed exactly once, this cannot always be the case for RMI due to transmission error
      – Either request or reply message may be lost
      – Either server or client may be crashed
  – The level of transparency
    • Make remote invocation as much like local invocation as possible
RMI Design Issues: Transparency

• Transparent remote invocation: like a local call
  – marshalling/unmarshalling
  – locating remote objects
  – accessing/syntax

• Differences between local and remote invocations
  – latency: a remote invocation is usually several order of magnitude
greater than that of a local one
  – availability: remote invocation is more likely to fail
  – errors/exceptions: failure of the network? server? hard to tell
    • syntax might need to be different to handle different local vs remote
ersors/exceptions (e.g. Argus)
  – consistency on the remote machine:
    • Argus: incomplete transactions, abort, restore states [as if the call was
never made]
5.4.2 Implementation of RMI

**Communication module**

- Two cooperating communication modules carry out the request-reply protocols: message type, requestID, remote object reference
  - Transmit request and reply messages between client and server
  - Implement specific invocation semantics
- The communication module in the server
  - selects the dispatcher for the class of the object to be invoked,
  - passes on local reference from remote reference module,
  - returns request

Figure 5.7 Role of proxy and skeleton in RMI
Implementation of RMI (cont.)

• Remote reference module
  – Responsible for translating between local and remote object references and for creating remote object references
  – remote object table: records the correspondence between local and remote object references
    • remote objects held by the process (B on server)
    • local proxy (B on client)
  – When a remote object is to be passed for the first time, the module is asked to create a remote object reference, which it adds to its table

• Servant
  – An instance of a class which provides the body of a remote object
  – handles the remote requests

• RMI software
  – Proxy: behaves like a local object, but represents the remote object
  – Dispatcher: look at the methodID and call the corresponding method in the skeleton
  – Skeleton: implements the method
  Generated automatically by an interface compiler
Implementation Alternatives of RMI

• Dynamic invocation
  – Proxies are static—interface complied into client code
  – Dynamic—interface available during run time
    • Generic invocation; more info in “Interface Repository” (COBRA)
    • Dynamic loading of classes (Java RMI)

• Binder
  – A separate service to locate service/object by name through table mapping for names and remote object references

• Activation of remote objects
  – Motivation: many server objects not necessarily in use all of the time
    • Servers can be started whenever they are needed by clients, similar to inetd
  – Object status: active or passive
    • active: available for invocation in a running process
    • passive: not running, state is stored and methods are pending
  – Activation of objects:
    • creating an active object from the corresponding passive object by creating a new instance of its class
    • initializing its instance variables from the stored state
  – Responsibilities of **activator**
    • Register passive objects that are available for activation
    • Start named server processes and activate remote objects in them
    • Keep track of the locations of the servers for remote objects that it has already activated
Implementation Alternatives of RMI (cont.)

• Persistent object stores
  – An object that is guaranteed to live between activations of processes is called a **persistent object**
  – Persistent object store: managing the persistent objects
    • stored in marshaled from on disk for retrieval
    • saved those that were modified
  – Deciding whether an object is persistent or not:
    • persistent root: any descendent objects are persistent (persistent Java, PerDiS)
    • some classes are declared persistent (Arjuna system)

• Object location
  – specifying a location: ip address, port #, …
  – location service for migratable objects
    • Map remote object references to their probable current locations
    • Cache/broadcast scheme (similar to ARP)
      – Cache locations
      – If not in cache, broadcast to find it
    • Improvement: forwarding (similar to mobile IP)
5.4.3 Distributed Garbage Collection

• Aim: ensure that an object
  – continues to exist if a local or remote reference to it is still held anywhere
  – be collected as soon as no object any longer holds a reference to it

• General approach: reference count

• Java's approach
  – the server of an object (B) keeps track of proxies
  – when a proxy is created for a remote object
    • addRef(B) tells the server to add an entry
  – when the local host's garbage collector removes the proxy
    • removeRef(B) tells the server to remove the entry
  – when no entries for object B, the object on server is deallocated
5.5 Case Study: Java RMI

import java.rmi.*;
import java.util.Vector;

public interface Shape extends Remote {
    int getVersion() throws RemoteException;
    GraphicalObject getAllState() throws RemoteException;
}

public interface ShapeList extends Remote {
    Shape newShape(GraphicalObject g) throws RemoteException;
    Vector allShapes() throws RemoteException;
    int getVersion() throws RemoteException;
}

import java.rmi.*;
import java.rmi.server.UnicastRemoteObject;
import java.util.Vector;

public class ShapeListServant extends UnicastRemoteObject implements ShapeList {
    private Vector theList; // contains the list of Shapes
    private int version;

    public ShapeListServant() throws RemoteException {
        ... // constructor implementation
    }

    public Shape newShape(GraphicalObject g) throws RemoteException {
        version++;
        Shape s = new ShapeServant(g, version);
        theList.addElement(s);
        return s;
    }

    public Vector allShapes() throws RemoteException {
        ... // implementation
    }

    public int getVersion() throws RemoteException {
        ... // implementation
    }
}
Java class ShapeListServer

public class ShapeListServer{
    public static void main(String args[]){
        System.setSecurityManager(new RMISecurityManager());
        try{
            ShapeList aShapeList = new ShapeListServant();
            Naming.rebind("Shape List", aShapeList );
            System.out.println("ShapeList server ready");
        }catch(Exception e) {
            System.out.println("ShapeList server main " + e.getMessage());
        }
    }
}

import java.rmi.*;
import java.rmi.server.*;
import java.util.Vector;
public class ShapeListClient{
    public static void main(String args[]){
        System.setSecurityManager(new RMISecurityManager());
        ShapeList aShapeList = null;
        try{
            aShapeList = (ShapeList) Naming.lookup("//bruno.ShapeList");
            Vector sList = aShapeList.allShapes();
        } catch(RemoteException e) {System.out.println(e.getMessage());
        }catch(Exception e) {System.out.println("Client: " + e.getMessage());
    }
}
void rebind (String name, Remote obj)
   This method is used by a server to register the identifier of a remote
   object by name, as shown in Figure 15.13, line 3.

void bind (String name, Remote obj)
   This method can alternatively be used by a server to register a remote
   object by name, but if the name is already bound to a remote object
   reference an exception is thrown.

void unbind (String name, Remote obj)
   This method removes a binding.

Remote lookup(String name)
   This method is used by clients to look up a remote object by name, as
   shown in Figure 15.15 line 1. A remote object reference is returned.

String [] list()
   This method returns an array of Strings containing the names bound in
   the registry.
Jini

- Jini technology is a service oriented architecture that defines a programming model which both exploits and extends Java technology to enable the construction of secure, distributed systems consisting of federations of well-behaved network services and clients
- Allow a potential subscriber in one Java Virtual Machine (JVM) to subscribe to and receive notifications of events in an object of interest in another JVM
- Main objects
  - event generators (publishers)
  - remote event listeners (subscribers)
  - remote events (events)
  - third-party agents (observers)
- An object subscribes to events by informing the event generator about the type of event and specifying a remote event listener as the target for notification
Java RMI Callbacks

• Callbacks
  – server notifying the clients of events
  – why?
    • polling from clients increases overhead on server
    • not up-to-date for clients to inform users
  – how
    • remote object (callback object) on client for server to call
    • client tells the server about the callback object, server put the client on a list
    • server call methods on the callback object when events occur
  – client might forget to remove itself from the list
    • lease--client expire
